Pandas Overview

```
In [ ]: #Read csv file
    df = pd.read_csv(".data/Salaries.csv")
```

Note: The above command has many optional arguments to fine-tune the data import process.

There is a number of pandas commands to read other data formats:

```
pd.read_excel('myfile.xlsx',sheet_name='Sheet1', index_col=None, na_values=['NA'])
pd.read_stata('myfile.dta')
pd.read_sas('myfile.sas7bdat')
pd.read_hdf('myfile.h5','df')
```

Exploring data frames

```
In [3]: #List first 5 records
df.head(5)
```

Out[3]:

| | rank | discipline | phd | service | sex | salary |
|---|------|------------|-----|---------|------|--------|
| 0 | Prof | В | 56 | 49 | Male | 186960 |
| 1 | Prof | Α | 12 | 6 | Male | 93000 |
| 2 | Prof | Α | 23 | 20 | Male | 110515 |
| 3 | Prof | Α | 40 | 31 | Male | 131205 |
| 4 | Prof | В | 20 | 18 | Male | 104800 |

exercises

- ✓ Try to read the first 10, 20, 50 records;
- ✓ Can you guess how to view the last few records;

Data Frame data types

| Pandas Type | Native Python Type | Description |
|---------------------------|---|---|
| object | string | The most general dtype. Will be assigned to your column if column has mixed types (numbers and strings). |
| int64 | int | Numeric characters. 64 refers to the memory allocated to hold this character. |
| float64 | float | Numeric characters with decimals. If a column contains numbers and NaNs(see below), pandas will default to float64, in case your missing value has a decimal. |
| datetime64, timedelta[ns] | N/A (but see the <u>datetime</u> module in Python's standard library) | Values meant to hold time data. Look into these for time series experiments. |

Data Frames attributes/methods

| df.attribut e | description |
|------------------|--|
| dtypes | list the types of the columns |
| columns | list the column names |
| axes | list the row labels and column names |
| ndim | number of dimensions |
| size | number of elements |
| shape | return a tuple representing the dimensionality |
| values | numpy representation of the data |

| df.method() | description |
|-----------------------------|--|
| head([n]), tail([n]) | first/last n rows |
| describe() | generate descriptive statistics (for numeric columns only) |
| max(), min() | return max/min values for all numeric columns |
| mean(), median() | return mean/median values for all numeric columns |
| std() | standard deviation |
| sample([n]) | returns a random sample of the data frame |
| dropna() | drop all the records with missing values |

Data Frames groupby method

Using "group by" method we can:

- Split the data into groups based on some criteria
- Calculate statistics (or apply a function) to each group

```
In [ ]: #Group data using rank
    df_rank = df.groupby(['rank'])
In [ ]: #Calculate mean value for each numeric column per each group
    df_rank.mean()
```

 rank
 service
 salary

 AssocProf
 15.076923
 11.307692
 91786.230769

 AsstProf
 5.052632
 2.210526
 81362.789474

 Prof
 27.065217
 21.413043
 123624.804348

Data Frames: Slicing

There are a number of ways to subset the Data Frame:

- one or more columns
- one or more rows
- a subset of rows and columns

Rows and columns can be selected by their position or label

• When selecting one column, it is possible to use single set of brackets, but the resulting object will be a Series (not a DataFrame):

```
In [ ]: #Select column salary:
    df['salary']
```

 When we need to select more than one column and/or make the output to be a DataFrame, we should use double brackets:

```
In [ ]: #Select column salary:
    df[['rank','salary']]
```

Data Frames: Selecting rows

Select a range of rows, we can specify the range using ":"

```
#Select rows by their position:
df[0:10]
```

Notice that the first row has a position 0, and the last value in the range is omitted: So for 0:10 range the first 10 rows are returned with the positions starting with 0 and ending with 9

Select a range of rows, using their labels by the method loc:

```
#Select rows by their labels:
df.loc[10:20,['rank','sex','salary']]
```

| | rank | sex | salary |
|----|------|------|--------|
| 10 | Prof | Male | 128250 |
| 11 | Prof | Male | 134778 |
| 13 | Prof | Male | 162200 |
| 14 | Prof | Male | 153750 |
| 15 | Prof | Male | 150480 |
| 19 | Prof | Male | 150500 |

Data Frames: method iloc

Select a range of rows and/or columns, using their positions by the method iloc:

```
df.iloc[:, 0] # First column
df.iloc[:, -1] # Last column
```

Data Frames: Sorting

We can sort the data by a value in the column. By default the sorting will occur in ascending order and a new data frame is return.

| Out[|] | | rank | discipline | phd | service | sex | salary |
|------|---|----|----------|------------|-----|---------|--------|--------|
| | | 55 | AsstProf | Α | 2 | 0 | Female | 72500 |
| | | 23 | AsstProf | Α | 2 | 0 | Male | 85000 |
| | | 43 | AsstProf | В | 5 | 0 | Female | 77000 |
| | | 17 | AsstProf | В | 4 | 0 | Male | 92000 |
| | | 12 | AsstProf | В | 1 | 0 | Male | 88000 |

Data Frames: Sorting

We can sort the data using 2 or more columns:

```
In [ ] df_sorted = df.sort_values( by =['service', 'salary'], ascending = [True, False])
    df_sorted.head(10)
```

| 0 | | rank | discipline | phd | service | sex | salary |
|-------|----|----------|------------|-----|---------|--------|--------|
| Out[] | 52 | Prof | Α | 12 | 0 | Female | 105000 |
| | 17 | AsstProf | В | 4 | 0 | Male | 92000 |
| | 12 | AsstProf | В | 1 | 0 | Male | 88000 |
| | 23 | AsstProf | Α | 2 | 0 | Male | 85000 |
| | 43 | AsstProf | В | 5 | 0 | Female | 77000 |
| | 55 | AsstProf | Α | 2 | 0 | Female | 72500 |
| | 57 | AsstProf | Α | 3 | 1 | Female | 72500 |
| | 28 | AsstProf | В | 7 | 2 | Male | 91300 |
| | 42 | AsstProf | В | 4 | 2 | Female | 80225 |
| | 68 | AsstProf | Α | 4 | 2 | Female | 77500 |

Missing Values

21

26

Missing values are marked as NaN

20 AsstProf NaN 4.0 4.0 Male 92000.0

Prof A NaN 19.0 Male 148750.0

Prof A 33.0 30.0 Male

NaN

Missing Values

There are a number of methods to deal with missing values in the data frame:

| df.method() | description |
|------------------------------|---|
| dropna() | Drop missing observations |
| dropna(how='all') | Drop observations where all cells is NA |
| dropna(axis=1, how='all') | Drop column if all the values are missing |
| dropna(thresh = 5) | Drop rows that contain less than 5 non-missing values |
| fillna(0) | Replace missing values with zeros |
| isnull() | returns True if the value is missing |
| notnull() | Returns True for non-missing values |

Missing Values

- When summing the data, missing values will be treated as zero
- If all values are missing, the sum will be equal to NaN
- cumsum() and cumprod() methods ignore missing values but preserve them in the resulting arrays
- Missing values in GroupBy method are excluded (just like in R)
- Many descriptive statistics methods have *skipna* option to control if missing data should be excluded. This value is set to *True* by default

Aggregation Functions in Pandas

- Aggregation computing a summary statistic about each group, i.e.
 - compute group sums or means
 - compute group sizes/counts
- Common aggregation functions:
 - min, max
 - count, sum, prod
 - mean, median, mode, mad
 - std, var

| df.method() | description |
|-----------------------|--|
| describe | Basic statistics (count, mean, std, min, quantiles, max) |
| min, max | Minimum and maximum values |
| mean, median, mode | Arithmetic average, median and mode |
| var, std | Variance and standard deviation |
| sem | Standard error of mean |
| skew | Sample skewness |
| kurt | kurtosis |

•

Aggregation Functions in Pandas

• agg() method are useful when multiple statistics are computed per column:

```
In [ ] flights[['dep_delay','arr_delay']].agg(['min','mean','max'])
```

| Out[]: | | dep_delay | arr_delay |
|--------|------|------------|------------|
| | min | -16.000000 | -62.000000 |
| | mean | 9.384302 | 2.298675 |
| | max | 351.000000 | 389.000000 |
